“Teamwork is essential. It allows you to blame someone else.”(Anonymous)

Part III: Recovery

- 11 Transaction Recovery
- 12 Crash Recovery: Notion of Correctness
- 13 Page-Model Crash Recovery Algorithms
- 14 Object-Model Crash Recovery Algorithms
- 15 Special Issues of Recovery
- 16 Media Recovery
- 17 Application Recovery

Chapter 14: Object-Model Crash Recovery

- **14.2 Overview of Redo-History Algorithms**

- 14.3 Simple Algorithm for 2-Layered Systems
- 14.4 Enhanced Algorithm for 2-Layered Systems
- 14.5 Complete Algorithm for General Executions
- 14.6 Lessons Learned

“This we know. All things are connected.” (Chief Seattle)

Conceptual Overview of Redo -History Algorithms

- *Analysis pass*: as in page model
- *Redo pass*: page-level redo for efficiency
- *Undo pass*: needs to invoke inverse high -level operations

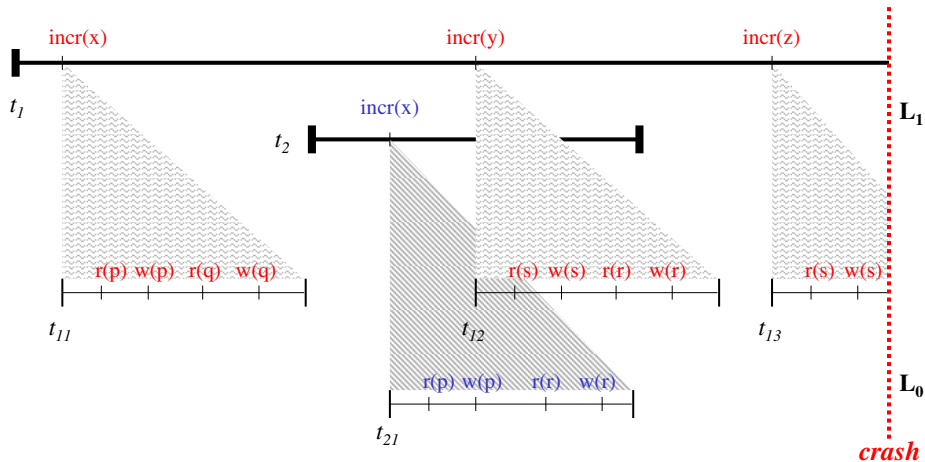

Problems:

- atomicity of high-level operations:
how to deal with partial effects of high-level operations
- idempotence of high-level operations:
how to detect and prevent duplicate executions
in situations where winners can follow losers

Solutions:

- page-level undo for partial high -level operations
- create CLEs for high-level inverse operations

Example for Object-Model Crash Recovery

Chapter 14: Object-Model Crash Recovery

- 14.2 Overview of Redo-History Algorithms
- **14.3 Simple Algorithm for 2-Layered Systems**
- 14.4 Enhanced Algorithm for 2-Layered Systems
- 14.5 Complete Algorithm for General Executions
- 14.6 Lessons Learned

Actions During Normal Operation

- Introduce separate logs for each layer, with separate instances of the log manager's data structures (e.g., log buffer)
 - Maintain L_0 log for page writes on behalf of subtransactions along with subcommit log entries for redo of completed subtransactions and undo of incomplete subtransactions
 - Maintain L_1 log for high-level inverse operations and transaction commit log entries
 - Both logs make use of CLEs
- } *page-model crash recovery for sub-transactions*

Log buffer forcing necessary for:

- L_0 log before a dirty page can be flushed
- L_1 log upon transaction commit, with L_0 log forced beforehand for transaction redo guarantee
- L_1 log before L_0 log is forced for transaction undo guarantee

Execution of High-Level Operations

```
exec (op, transid, inputparams, ↑returnvalues, s):  
  subbegin ( ) ↑subtransid;  
  execute operation;  
  newlogentry.LogSeqNo := s;  
  newlogentry.ActionType := exec;  
  newlogentry.TransId := transid;  
  newlogentry.SubtransId := subtransid;  
  newlogentry.UndoInfo :=  
    information on the inverse operation and its parameters;  
  newlogentry.PreviousSeqNo := ActiveTrans[transid].LastSeqNo;  
  ActiveTrans[transid].LastSeqNo := s;  
  L1LogBuffer += newlogentry;  
  subcommit (subtransid);
```

Simple 2-Level Crash Recovery Algorithm

- L_0 recovery first identifies winner subtransactions, performs redo for these and undo for incomplete subtransactions
- L_1 recovery then identifies loser transactions, performs undo by traversing the corresponding NextUndoSeqNo backward chains:
 - an inverse operation is initiated iff the corresponding forward subtransaction was a winner
 - inverse operation executions create CLEs in the L_1 log and are treated like subtransactions during normal operation

restart ():

```
 $L_0$  analysis pass ( ) returns losers, winners, DirtyPages;  
 $L_0$  redo pass ( );  
 $L_0$  undo pass ( );  
 $L_1$  analysis pass ( );  
 $L_1$  undo pass ( );
```

Efficient Testing of Winner Subtransactions

Problem:

L_1 undo step needs to be invoked iff the corresponding subtransaction is an L_0 winner
→ need efficient test without explicit L_0 winner list

Solution:

- Include L_0 subbegin LSN in L_1 log entry for high-level operation
- L_0 analysis pass should identify maximum subbegin LSN as a “survivor mark” and explicitly identifies loser subtransactions
- L_1 undo pass test “presence” of high-level operation f_{ij} as follows:
 - if subbegin LSN in L_1 log entry for f_{ij} is larger than survivor mark then f_{ij} must be a loser subtransaction
 - otherwise (i.e., there is L_0 evidence of f_{ij}), if f_{ij} is not a loser subtransaction then it must be a winner subtransaction

L_1 Undo Pass of Simple 2-Level Algorithm (1)

```
 $L_1$  undo pass ( ):
  ActiveTrans := empty;
  for each t in L1 losers do
    ActiveTrans += t;
    ActiveTrans[t].LastSeqNo := losers[t].LastSeqNo;
  end /*for*/;
  while there exists t in losers
    such that losers[t].LastSeqNo <> nil do
    nexttrans := TransNo in losers
      such that losers[nexttrans].LastSeqNo =
        max {losers[x].LastSeqNo | x in losers};
    nextentry := losers[nexttrans].LastSeqNo;
    if StableLog[nextentry].ActionType = compensation then
      if StableLog[nextentry].CompensatingSubtransId
        is in L0 winners then
        losers[nexttrans].LastSeqNo :=
          StableLog[nextentry].NextUndoSeqNo else
        losers[nexttrans].LastSeqNo :=
          StableLog[nextentry].PreviousSeqNo;
      end /*if*/;
    end /*if*/;
```

L₁ Undo Pass of Simple 2-Level Algorithm (2)

```
if StableLog[nextentry].ActionType = exec then
  if StableLog[nextentry].SubtransId is in L0 winners
  then
    subbegin ( );
    newlogentry.LogSeqNo := new sequence number;
    newlogentry.ActionType := compensation;
    newlogentry.PreviousSeqNo :=
      ActiveTrans[transid].LastSeqNo;
    newlogentry.NextUndoSeqNo := nextentry.PreviousSeqNo;
    ActiveTrans[transid].LastSeqNo :=
      newlogentry.LogSeqNo;
    LogBuffer += newlogentry;
    execute inverse operation
      according to StableLog[nextentry].UndoInfo;
    subcommit ( );
  end /*if*/;
  losers[nexttrans].LastSeqNo :=
    StableLog[nextentry].PreviousSeqNo;
end /*if*/;
```

L₁ Undo Pass of Simple 2-Level Algorithm (3)

```
if StableLog[nextentry].ActionType = begin
then
    newlogentry.LogSeqNo := new sequence number;
    newlogentry.ActionType := rollback;
    newlogentry.TransId := StableLog[nextentry].TransId;
    newlogentry.PreviousSeqNo :=
        ActiveTrans[transid].LastSeqNo;
    LogBuffer += newlogentry;
    ActiveTrans -= transid;
    losers -= transid;
end /*if*/;

end /*while*/;
force ( );
```

Enhanced 2-Level Crash Recovery Algorithm

combine L_0 log and L_1 log into a single log

- simplifies log forcing: log buffer forcing as in page model
- simplifies state testing by L_1 undo:
by creating the L_1 log entry for the inverse operation at the end of the subtransaction and interpreting it also as an L_0 subcommit, the L_1 undo pass does no longer need to test for L_0 winners
- can combine two analysis passes into one
- can combine two undo passes into one
by using the NextUndoSeqNo backward chain as follows:
 - an L_0 write log entry points to the preceding write
 - in the same subtransaction
 - the very first L_0 write log entry of a subtransaction points to the L_1 log entry of the preceding subtransaction
 - an L_0 or L_1 CLE points to the predecessor of the compensated action

NextUndoSeqNo Backward Chaining in Enhanced 2-Level Crash Recovery Algorithm

combined L_0/L_1 log ...

L_0/L_1 Undo Pass of Enhanced 2-Level Algorithm (1)

```
undo pass ( ):
  ActiveTrans := empty;
  for each t in losers do
    ActiveTrans += t;
    ActiveTrans[t].LastSeqNo := losers[t].LastSeqNo;
  end /*for*/;
  while there exists t in losers such that
    losers[t].LastSeqNo <> nil do
    nextttrans = TransNo in losers
      such that losers[nextttrans].LastSeqNo =
        max {losers[x].LastSeqNo | x in losers};
    nextentry := losers[nextttrans].LastSeqNo;

    if StableLog[nextentry].ActionType = compensation then
      losers[nextttrans].LastSeqNo :=
        StableLog[nextentry].NextUndoSeqNo;
    end /*if*/;
```

Correctness of Enhanced 2-Level Algorithm

Theorem 14.1:

The enhanced 2-level crash recovery method,
with 3 passes over the combined log, performs correct recovery.

Proof sketch:

The following invariant holds at each point of the undo pass:

\forall log sequence numbers $s \in \text{StableLog}$ such that

$s = \text{ActiveTrans}[t].\text{LastSeqNo}$ for some loser transaction t :

\forall operations $o \in \text{StableLog}$:

(o belongs to t) \Rightarrow

(o is reachable along $\text{ActiveTrans}[t].\text{NextUndoSeqNo}$

$\Leftrightarrow o \in \text{CachedDatabase}$)

Lessons Learned

- The redo-history paradigm can be extended to object-model crash recovery.
- State-of-the-art algorithms are based on:
 - page-oriented redo of winners and losers
 - log entries of all levels in a single log, to facilitate a single undo pass
 - log entries for high-level operations are at the same time sub-commit log entries to ensure the operation atomicity
 - for undo, log entries of all levels are appropriately linked in the NextUndoSeqNo backward chain
 - during undo, CLEs are created to track progress and ensure idempotence
 - during undo, the execution of high-level inverse operations requires the creation of low-level redo log entries to ensure operation atomicity
